

# **Introduction to Parsing**

Detmar Meurers: Intro to Computational Linguistics I  
OSU, LING 684.01

# Overview

- What is a parser?
- Under what criteria can they be evaluated?
- Parsing strategies
  - top-down vs. bottom-up
  - left-right vs. right-left
  - depth-first vs. breadth-first
- Implementing different types of parsers:
  - Basic top-down and bottom-up
  - More efficient algorithms

# Parsers and criteria to evaluate them

- Function of a parser:
  - grammar + string  $\rightarrow$  analysis trees
- Main criteria for evaluating parsers:
  - correctness
  - completeness
  - efficiency

# Correctness

A parser is **correct** iff for every grammar and for every string, every analysis returned by parser is an actual analysis.

Correctness is nearly always required (unless simple post-processor could eliminate wrong analyses)

# Completeness

A parser is **complete** iff for every grammar and for every string, every correct analysis is found by the parser.

- In theory, always desirable.
- In practice, essential to find the 'relevant' analysis first (possibly using heuristics).
- For grammars licensing an infinite number of analyses this means: there is no analysis that the parser could not find.

# Efficiency

- One can reason about complexity of (parsing) algorithms by considering how it will deal with bigger and bigger examples.
- For practical purposes, the factors ignored by such analyses are at least as important.
  - profiling using typical examples important
  - finding the (relevant) first parse vs. all parse
- Memoization of complete or partial results is essential to obtain efficient parsing algorithms.

# Complexity classes

If  $n$  is the length of the string to be parsed, one can distinguish the following complexity classes:

- **constant**: amount of work does not depend on  $n$
- **logarithmic**: amount of work behaves like  $\log_k(n)$  for some constant  $k$
- **polynomial**: amount of work behaves like  $n^k$ , for some constant  $k$ . This is sometimes subdivided into the cases
  - **linear** ( $k = 1$ )
  - **quadratic** ( $k = 2$ )
  - **cubic** ( $k = 3$ )
  - . . .
- **exponential**: amount of work behaves like  $k^n$ , for some constant  $k$ .

# Complexity and the Chomsky hierarchy

Grammar type	Worst-case complexity of recognition
regular (3)	linear
context-free (2)	cubic ( $n^3$ )
context-sensitive (1)	exponential
general rewrite (0)	undecidable

Recognition with type 0 grammars is **recursively enumerable**: if a string  $x$  is in the language, the recognition algorithm will succeed, but it will not return if  $x$  is not in the language.

# Parsing strategies

1. What do we start from?
  - top-down vs. bottom-up
2. In what order is the string or the RHS of a rule looked at?
  - left-to-right, right-to-left, island-driven, . . .
3. How are alternatives explored?
  - depth-first vs. breadth-first

# Direction of processing I: Top-down

**Goal-driven** processing is Top-down:

- Start with the start symbol
- Derive sentential forms.
- If the string is among the sentences derived this way, it is part of the language.

## Direction of processing II: Bottom-up

**Data-driven** processing is Bottom-up:

- Start with the sentence.
- For each substring  $\sigma$  of each sentential form  $\alpha\sigma\beta$ , find each grammar rule  $N \rightarrow \sigma$  to obtain all sentential forms  $\alpha N\beta$ .
- If the start symbol is among the sentential forms obtained, the sentence is part of the language.

Problem: Epsilon rules ( $N \rightarrow \epsilon$ ).

# The order in which one looks at a RHS

Left-to-Right

- Use the leftmost symbol first, continuing with the next to its right

## How are alternatives explored? I. Depth-first

- At every choice point: Pursue a single alternative completely before trying another alternative.
- State of affairs at the choice points needs to be remembered. Choices can be discarded after unsuccessful exploration.
- Depth-first search is not necessarily complete.

Problem for top-down, left-to-right, depth-first processing:

- left-recursion  
For example, a rule like  $N' \rightarrow N' PP$  leads to non-termination.

## How are alternatives explored? II. Breadth-first

- At every choice point: Pursue every alternative for one step at a time.
- Requires serious bookkeeping since each alternative computation needs to be remembered at the same time.
- Search is guaranteed to be complete.

# Compiling and executing DCGs in Prolog

- DCGs are a grammar formalism supporting any kind of parsing regime.
- The standard translation of DCGs to Prolog plus the proof procedure of Prolog results in a parsing strategy which is
  - top-down
  - left-to-right
  - depth-first

# Implementing parsers

- Data structures: a parser configuration
- Top-down parsing
  - formal characterization
  - Prolog implementation
- Bottom-up parsing
  - formal characterization
  - Prolog implementation
- Towards more efficient parsers:
  - Left-corner
  - Remembering subresults

## An example grammar (parser/simple/grammar.pl)

```
% defining grammar rule operator
:- op(1100,xfx,'--->').
```

```
% lexicon:
```

```
vt ---> [saw].
det ---> [the].
det ---> [a].
n ---> [dragon].
n ---> [boy].
adj ---> [young].
```

```
% syntactic rules:
```

```
s ---> [np, vp].
vp ---> [vt, np].
np ---> [det, n].
n ---> [adj, n].
```

## A parser configuration

Assuming a left-to-right order of processing, a **configuration** of a parser can be encoded by a pair of

- a stack as auxiliary memory
- the string remaining to be recognized

More formally, for a grammar  $G = (N, \Sigma, S, P)$ , a parser configuration is a pair  $\langle \alpha, \tau \rangle$  with  $\alpha \in (N \cup \Sigma)^*$  and  $\tau \in \Sigma^*$

# Top-down parsing

- **Start configuration** for recognizing a string  $\omega$ :  $\langle S, \omega \rangle$
- **Available actions:**
  - **consume:** remove an expected terminal  $a$  from the string  
 $\langle a\alpha, a\tau \rangle \mapsto \langle \alpha, \tau \rangle$
  - **expand:** apply a phrase structure rule  
 $\langle A\beta, \tau \rangle \mapsto \langle \alpha\beta, \tau \rangle$  if  $A \rightarrow \alpha \in P$
- **Success configuration:**  $\langle \epsilon, \epsilon \rangle$

## A top-down parser in Prolog (parser/simple/td\_parser.pl)

```
:- op(1100,xfx,'--->').
```

```
% Start
```

```
td_parse(String) :- td_parse([s],String).
```

```
% Success
```

```
td_parse([],[]).
```

```
% Consume
```

```
td_parse([H|T],[H|R]) :-  
    td_parse(T,R).
```

```
% Expand
```

```
td_parse([A|Beta],String) :-  
    (A ---> Alpha),  
    append(Alpha,Beta,Stack),  
    td_parse(Stack,String).
```

## Bottom-up parsing

- **Start configuration** for recognizing a string  $\omega$ :  $\langle \epsilon, \omega \rangle$
- **Available actions:**
  - **shift:** turn to the next terminal  $a$  of the string  
 $\langle \alpha, a\tau \rangle \mapsto \langle \alpha a, \tau \rangle$
  - **reduce:** apply a phrase structure rule  
 $\langle \beta\alpha, \tau \rangle \mapsto \langle \beta A, \tau \rangle$  if  $A \rightarrow \alpha \in P$
- **Success configuration:**  $\langle S, \epsilon \rangle$

## A shift-reduce parser in Prolog (parser/simple/sr\_parser.pl)

```
:- op(1100,xfx,'--->').

sr_parse(String) :- sr_parse([],String).      % Start

sr_parse([s],[]).                             % Success

sr_parse(Stack,String) :-                    % Reduce
    append(Beta,Alpha,Stack),
    (A ---> Alpha),
    append(Beta,[A],NewStack),
    sr_parse(NewStack,String).

sr_parse(Stack,[Word|String]) :-            % Shift
    append(Stack,[Word],NewStack),
    sr_parse(NewStack,String).
```
